🚀 Getting Started with Fast Blur

1. Import the Asset

- Import the **Fast Blur** package into your Unity 6+ project using the Universal Render Pipeline (URP).

2. Add the Renderer Feature

- Go to your **URP Renderer Asset** (e.g., `ForwardRenderer`).
- In the **Inspector**, scroll down to **Renderer Features**.
- Click **"Add Renderer Feature"** → select **Blur Renderer**.

3. Create or Modify a Volume

- In your scene, add a **Post-Processing Volume**:
  - GameObject → Volume → Global Volume (or Local Volume, depending on your use case).
- Assign a **Volume Profile** (or create a new one).

4. Add the Fast Blur Override

- Inside the Volume Profile, click **"Add Override"** → select **Post-processing** → **Blur**.
- Adjust the **Blur Intensity** slider to control the effect strength.

5. Done!

- The blur will now render as a fullscreen effect and dynamically respond to volume blending, transitions, and runtime changes.

💡 Tips

- To smoothly blend between blur states, animate the **Blur Intensity** via scripts, timeline, or volume blending.
- Use local volumes to create blur zones or trigger UI background blur dynamically.
- Works great for menus, pause screens, cutscenes, or real-time VFX.
